**Please find below and/or attached an Office communication concerning this application or proceeding.**

The time period for reply, if any, is set in the attached communication.

### Office Action Summary

**Application No.**

10/825,654

**Applicant(s)**

KISHORE ET AL.

**Examiner**

NIMA MAHMOUDZADEH

**Art Unit**

2419

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --  
**Period for Reply**

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

**Status**

- 1) ☒ Responsive to communication(s) filed on 30 April 2009.
- 2a) ☐ This action is **FINAL**. 2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

**Disposition of Claims**

- 4) ☒ Claim(s) 1-26 and 31-34 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1-26 and 31-34 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

**Application Papers**

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on \_\_\_\_\_ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

**Priority under 35 U.S.C. § 119**

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some \* c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
  2. ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
  3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

\* See the attached detailed Office action for a list of the certified copies not received.

**Attachment(s)**

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☐ Information Disclosure Statement(s) (PTO-8508)  
Paper No(s)/Mail Date \_\_\_\_\_
- 4) ☐ Interview Summary (PTO-413)  
Paper No(s)/Mail Date \_\_\_\_\_
- 5) ☐ Notice of Informal Patent Application
- 6) ☐ Other: \_\_\_\_\_

**DETAILED ACTION**

***Continued Examination Under 37 CFR 1.114***

1. A request for continued examination under 37 CFR 1.114, including the fee set forth in 37 CFR 1.17(e), was filed in this application after final rejection. Since this application is eligible for continued examination under 37 CFR 1.114, and the fee set forth in 37 CFR 1.17(e) has been timely paid, the finality of the previous Office action has been withdrawn pursuant to 37 CFR 1.114. Applicant's submission filed on 04/30/2009 has been entered.

***Claim Rejections - 35 USC § 102***

2. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless –

(e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

3. Claims 1-6, 8, 10, 21, 23, 31, and 32 are rejected under 35 U.S.C. 102(e) as being anticipated by Erimli (US Patent No. 6,980,520).

**Regarding claim 1,** (Currently Amended) Erimli teaches a method of managing flow of datagram traffic, the method comprising:

receiving datagrams from a first port of a first device (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right)

at a first port of a second device (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces) using a pathway that is operably connected to a second port of the first device and a second port of the second device (Fig. 1, connection between left and right multiport switch);

determining, at the second device (Column 7, lines 1-10 discloses a second switch receives –detects- the MAC control pause frame and suspends transmission to multiport switch 180 of data frames having the source address included in the pause frame. When a second switch receives the pause frame, it stops sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via the network), an individual port on the first device that is causing oversubscription of the first port of the second device (Column 7, lines 1-10 discloses the second switch may also identify the port associated with the source address included in the pause frame. Also, column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address);

transmitting a pause frame from the second device to the first device (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address), the pause frame causing the individual port to pause transmission of the datagrams using the pathway (Column 8,

lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address. Fig. 1); and

receiving datagrams from a third port of the first device at the first port of the second device using the pathway while the individual port on the first device is paused (Fig. 1 and Fig. 3. Also, column 10, lines 63-65 discloses the multiport switch 180B, however, may continue to transmit data frames to multiport switch 180A having other source addresses).

**FIG. 3**

**Regarding claim 2, (Currently Amended)** Erimli teaches the method of claim 1, further comprising:

Re-activating the individually paused port including transmitting a re-activation signal to the paused port (Column 1, lines 32-41 discloses the pause frame instructs the stations receiving the pause frame to stop sending data for a period of time).

**Regarding claim 3, (Currently Amended)** Erimli teaches the method of claim 1, further comprising:

re-activating the individually paused port pursuant to the detection of a condition wherein the first port of the second device has datagram traffic flowing there through in an amount that is below a lower trigger value (Column 8, lines 58-67 discloses the congestion signal may include the source address of the data packet that caused the free buffer queue to reach the predetermined threshold).

**Regarding claim 4, (Currently Amended)** Erimli teaches the method of claim 1, further comprising:

re-activating the individually paused port pursuant to the passage of a pre-determined time increment (Column 1, lines 32-41 discloses the pause frame instructs the stations receiving the pause frame to stop sending data for a period of time).

**Regarding claim 5, (Currently Amended)** Erimli teaches the method of claim 1, wherein the transmitting the pause frame comprises using in-band control frames to pause the individual port (Fig. 3, discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information. Also, FIG. 6 illustrates an exemplary MAC control pause frame 600. The MAC control pause frame 600 also includes a source address field 610 that identifies the source address associated with the frame causing the congestion).

**Regarding claim 6, (Currently Amended)** Erimli teaches the method of claim 1, wherein the transmitting the pause frame comprises using separate pathways between the first and second networked devices to transmit datagrams and control frames (Fig. 2, discloses the data bus 215 may include one or more conductors that connect the receiver 205, the transmitter 210, the IRC 245, and the external memory interface 265. Also, Fig. 3, discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information).

**Regarding claim 8, (Currently Amended)** Erimli teaches the method of claim 1, wherein the transmitting the pause frame comprises referencing a listing of ports that are over-subscribed (Fig. 6. field 610).

**Regarding claim 10, (Currently Amended)** Erimli teaches the method of claim 1, wherein the determining comprises determining individual ports on devices other than

the first and second device (Column 7, lines 1-29 and FIG. 3 illustrates an exemplary implementation of the present invention in which two multiport switches, labeled 180A and 180B, are coupled together).

**Regarding claim 21,** (Currently Amended) Erimli teaches a communications device comprising:

a first communications means for receiving datagrams from a first port of a first data distribution means device (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right) at a first port of a second data distribution means (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces);

determining means for determining, at the second data distribution means (Column 7, lines 1-10 discloses a second switch receives –detects- the MAC control pause frame and suspends transmission to multiport switch 180 of data frames having the source address included in the pause frame. When a second switch receives the pause frame, it stops sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via the network), individual ports on the first data distribution means that cause oversubscription of the first port of the second data distribution means (Column 7, lines 1-10 discloses the second switch may also identify the port associated with the source address included in the pause frame. Also, column 8, lines 45-48 discloses if a

resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address);

control means for selectively pausing the individual ports that are causing oversubscription of the first port of the second data distribution means (Column 7, lines 1-10 discloses the second switch may also identify the port associated with the source address included in the pause frame. Also, column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address); and

means for transferring receiving datagrams from a second port of the first data distribution means (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address) at the first port of the second data distribution means, while the individual ports are paused (Column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address. Fig. 1).

**.Regarding claim 23, (Currently Amended)** Erimli teaches the device of claim 21, further comprising storage means for storing information concerning which ports in the network are over-subscribed (Fig. 3, element 240).

**27-30. (Cancelled)**

**Regarding claim 31, (New)** Erimli teaches a communications device comprising:

an interconnect port controller configured to receive datagrams from a first port of a first device at a first port of the device; and

a memory unit controller configured to determine, at the device, individual ports on the first device that cause oversubscription of the first port of the device (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right), wherein

the interconnect portion controller is configured to selectively pause the individual ports of the first device that are causing oversubscription of the first port of the device (Fig. 3, Flow Control Logic 225), and to receive datagrams from a second port of the first device at the first port of the device, while the individual ports are paused (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces. Also, column 10, lines 63-67).

**Regarding claim 32,** (New) Erimli teaches the device of claim 31, further comprising:

a memory unit configured to store information concerning which ports in the device are over-subscribed (Fig. 2, discloses the data bus 215 may include one or more conductors that connect the receiver 205, the transmitter 210, the IRC 245, and the external memory interface 265. Also, Fig. 3, discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information)..

***Claim Rejections - 35 USC § 103***

4. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

This application currently names joint inventors. In considering patentability of the claims under 35 U.S.C. 103(a), the examiner presumes that the subject matter of the various claims was commonly owned at the time any inventions covered therein were made absent any evidence to the contrary. Applicant is advised of the obligation under 37 CFR 1.56 to point out the inventor and invention dates of each claim that was not commonly owned at the time a later invention was made in order for the examiner to consider the applicability of 35 U.S.C. 103(c) and potential 35 U.S.C. 102(e), (f) or (g) prior art under 35 U.S.C. 103(a).

5. Claim 7 is rejected under 35 U.S.C. 103(a) as being unpatentable over Erimli in view of Kim et al. (US Patent Publication No. 2003/0219027).

**Regarding claim 7,** (Currently Amended) Erimli teaches the method of claim 1, wherein the transmitting the pause frame (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address) but fail to teach using a non-memory-consuming communication to pause the individual port. However, Kim et al. teach using a non-memory-consuming communication to pause the individual port (Paragraph [0007] discloses the non-memory semiconductor performs a traffic transmission between ports in network

equipment such as a router and switch, and performs a programming for an intelligent switching function in such a way that various kinds of multimedia Internet traffic services are available).

Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to modify the method of Erimli to include the non-memory feature taught by Kim et al. in order to increase the speed of the communication and reduce the delay that is caused by buffers.

6. Claim 9 is rejected under 35 U.S.C. 103(a) as being unpatentable over Erimli in view of Montalvo et al. (US Patent Publication No. 2003/0147385).

**Regarding claim 9,** (Currently Amended) Erimli teaches the method of claim 8, wherein the transmitting the pause frame (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address) but fail to teach the method wherein periodically updating the listing of ports that are over-subscribed. However, Monralvo et al. teach the method wherein periodically updating the listing of ports that are over-subscribed (Paragraph [0054] discloses the mapping in the table 512 in ingress switching device 110 is reassigned to change the port assignment such that the egress traffic of an over-subscribed intermediate port on the egress switching device 160 is diverted to an under-subscribed intermediate port. The QID-to-intermediate port mapping is preferably updated periodically, every sixty seconds in some embodiments).

Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to modify the method of Erimli to include the periodically

updating the table of paused ports taught by Montalvo et al. in order to have the updated information and as a result less delay and increased precision.

7. Claims 11-20, 24, 26, 33, and 34 are rejected under 35 U.S.C. 103(a) as being unpatentable over Erimli in view of Levine (US Patent No. 6,504,818).

**Regarding claim 11**, (Currently Amended) Erimli teaches a method of managing flow of datagram traffic, the method comprising:

receiving datagrams from a first port of a first device (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right) at a first port of a second device (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces) using a pathway that is operably connected to a second port of the first device and a second port of the second device (Fig. 1, connection between left and right multiport switch);

determining, at the second device (Column 7, lines 1-10 discloses a second switch receives –detects- the MAC control pause frame and suspends transmission to multiport switch 180 of data frames having the source address included in the pause frame. When a second switch receives the pause frame, it stops sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via the network), an individual port on the first device that is causing oversubscription of the first port of the second device (Column 7, lines 1-10 discloses the second switch may also identify the port

associated with the source address included in the pause frame. Also, column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address);

signaling the first port of the first device to continue sending send fewer datagrams to the first port of the second device (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address), based on the determining when an over-subscription is detected at the first port of the second device (Column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address. Fig. 1); and

receiving datagrams from a third port of the first device at the first port of the second device using the pathway that is operably connected to the second port of the first device and the second port of the second device, while continuing to receive the datagrams from the first port of the first device at the first port of the second device (Fig. 1 and Fig. 3. Also, column 10, lines 63-65 discloses the multiport switch 180B, however, may continue to transmit data frames to multiport switch 180A having other source addresses). But fail to teach the transmission and reception at a reduced rate. However, Levine teaches the transmission and reception datagrams at a reduced rate (Column 1, lines 45 - 65 discloses if a global congestion threshold is exceeded, the egress port generates a feedback control signal to all sources causing the sources to reduce the

rate at which they deliver data to the network for delivery to the egress port. Other control schemes provide for local congestion detection, in which the egress port identifies individual sources from which it receives data. If data received from any one source exceeds a local congestion threshold associated with the source, the egress port generates a second type of feedback control signal to the source causing it to reduce the rate at which it generates data for the egress port).

Therefore, it would be obvious to one of ordinary skill in the art at the time the invention was made to modify a method of Erimli to include the rate reduction taught by Levine in order to reduce delay and increase the dependability of the network communications.

**Regarding claim 12,** (Previously Presented) Erimli in view of Levine teach the method of claim 11, Erimli further teaches wherein the signaling comprises signaling the first port of the first device to send datagrams in proportion to a total number of datagrams attempting to reach the first port of the second device (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces).

**Regarding claim 14,** (Previously Presented) Erimli in view of Levine teach the method of claim 11, Erimli further teaches the method wherein the signaling comprises broadcasting a signal that alerts ports on the network that the first port of the second device is over-subscribed (Column 8, lines 4-15 discloses multicasting which is a controlled broadcast).

**Regarding claim 15,** (Currently Amended) Erimli in view of Levine teach the method of claim 11, Erimli further teaches the method wherein the receiving datagrams from a first port of a first device at a first port of a second device comprises referencing a listing of ports on the network that are over-subscribed before transferring a datagram between the first port of the first device to the first port of the second device (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces).

**Regarding claim 16,** (Currently Amended) Erimli in view of Levine teach the method of claim 11, Erimli further teaches the method further comprising: resuming unrestricted datagram receipt at the first port of the second device including broadcasting a signal (Column 1, lines 32-41 discloses the pause frame instructs the stations receiving the pause frame to stop sending data for a period of time. Also, column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces).

**Regarding claim 17,** (Currently Amended) Erimli in view of Levine teach the method of claim 11, Erimli further teaches the method further comprising: resuming unrestricted datagram receipt at the first port of the second device when a total number of datagrams attempting to reach the first port of the second device falls below a lower trigger value (Column 8, lines 58-67 discloses the congestion signal may include the

source address of the data packet that caused the free buffer queue to reach the predetermined threshold).

**Regarding claim 18, (Currently Amended)** Erimli in view of Levine teach the method of claim 11, Erimli further teach the method further comprising: resuming unrestricted datagram receipt at the first port of the second device after passage of a pre-determined time increment (Column 1, lines 32-41 discloses the pause frame instructs the stations receiving the pause frame to stop sending data for a period of time).

**Regarding claim 19, (Previously Presented)** Erimli in view of Levine teach the method of claim 11, Erimli further teach the method wherein the signaling comprises using in-band control frames (Fig. 3, discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information. Also, FIG. 6 illustrates an exemplary MAC control pause frame 600. The MAC control pause frame 600 also includes a source address field 610 that identifies the source address associated with the frame causing the congestion).

**Regarding claim 20, (Previously Presented)** Erimli in view of Levine teach the method of claim 11, Erimli further teaches the method wherein the signaling comprises using a separate link to transmit control frames (Fig. 2, discloses the data bus 215 may include one or more conductors that connect the receiver 205, the transmitter 210, the IRC 245, and the external memory interface 265. Also, Fig. 3, discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information).

**Regarding claim 24,** (Currently Amended) Erimli teaches a communications device comprising:

first communications means for transferring receiving datagrams from a first port of a first data distribution means (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right) at a first port of a second data distribution means (Column 3, lines 53-65 discloses the transceivers 130 may include 10/100 Mb/s physical layer transceivers that communicate with the multiport switches 180 via respective serial media independent interfaces or reduced media independent interfaces);

determining means, at the second device (Column 7, lines 1-10 discloses a second switch receives –detects- the MAC control pause frame and suspends transmission to multiport switch 180 of data frames having the source address included in the pause frame. When a second switch receives the pause frame, it stops sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via the network), for determining an individual port on the first data distribution means that is causing oversubscription of the first port of the second data distribution means (Column 7, lines 1-10 discloses the second switch may also identify the port associated with the source address included in the pause frame. Also, column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address);

control means for signaling the first port of the first data distribution means to send datagrams to the first port of the second data distribution means (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address), based on the determining when an over subscription is detected at the first port of the second data distribution means (Column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address. Fig. 1); and

means for transferring datagrams from a second port of the first data distribution means at the first port of the second data distribution means, while continuing to receive datagrams from the first port of the first data distribution means at the first port of the second data distribution means (Fig. 1 and Fig. 3. Also, column 10, lines 63-65 discloses the multiport switch 180B, however, may continue to transmit data frames to multiport switch 180A having other source addresses). But fail to teach the transmission and reception at a reduced rate. However, Levine teaches the transmission and reception datagrams at a reduced rate (Column 1, lines 45 - 65 discloses if a global congestion threshold is exceeded, the egress port generates a feedback control signal to all sources causing the sources to reduce the rate at which they deliver data to the network for delivery to the egress port. Other control schemes provide for local congestion detection, in which the egress port identifies individual sources from which it receives data. If data received from any one source exceeds a local congestion threshold associated with the source, the egress port generates a second type of

feedback control signal to the source causing it to reduce the rate at which it generates data for the egress port).

Therefore, it would be obvious to one of ordinary skill in the art at the time the invention was made to modify a method of Erimli to include the rate reduction taught by Levine in order to reduce delay and increase the dependability of the network communications.

**Regarding claim 26,** (Currently Amended) Erimli in view of Levine teach the device of claim 24, Erimli further teaches the device further comprising:

storage means for storing information concerning which ports in the network are over-subscribed (Fig. 3, element 225).

**Regarding claim 33,** (New) Erimli teaches a communications device comprising:  
an interconnect port controller configured to receive datagrams from a first port of a first device at a first port of the device (Fig. 1, data transmission from element 110 of the left Multiport Switch to element 110 of element 180 on the right. Also, Fig. 3, element 225); and

a memory unit controller configured to determine, at the device, individual ports on the first device that cause oversubscription of the first port of the device (Column 7, lines 1-10 discloses a second switch receives –detects- the MAC control pause frame and suspends transmission to multiport switch 180 of data frames having the source address included in the pause frame. When a second switch receives the pause frame, it stops sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via

the network. Also, column 8, lines 45-48 discloses if a resource on the multiport switch 180A becomes congested, the multiport switch 180A may selectively request suspension of data transmissions from a particular source address), wherein

the interconnect port controller is configured to signal the first port of the first device (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address) to continue sending datagrams to the first port of the second device, based on the determining, and configured to receive datagrams from the first port of the first device at the first port of the device (Fig. 1 and Fig. 3. Also, column 10, lines 63-65 discloses the multiport switch 180B, however, may continue to transmit data frames to multiport switch 180A having other source addresses). But fail to teach the transmission and reception at a reduced rate. However, Levine teaches the transmission and reception datagrams at a reduced rate (Column 1, lines 45 - 65 discloses if a global congestion threshold is exceeded, the egress port generates a feedback control signal to all sources causing the sources to reduce the rate at which they deliver data to the network for delivery to the egress port. Other control schemes provide for local congestion detection, in which the egress port identifies individual sources from which it receives data. If data received from any one source exceeds a local congestion threshold associated with the source, the egress port generates a second type of feedback control signal to the source causing it to reduce the rate at which it generates data for the egress port).

Therefore, it would be obvious to one of ordinary skill in the art at the time the invention was made to modify a method of Erimli to include the rate reduction taught by

Levine in order to reduce delay and increase the dependability of the network communications.

**Regarding claim 34, (New)** Erimli in view of Levine teach the device of claim 33 , Erimli further teaches the device further comprising:

a memory unit configured to store information concerning which ports in the network are over-subscribed (Fig. 2, discloses the data bus 215 may include one or more conductors that connect the receiver 205, the transmitter 210, the IRC 245, and the external memory interface 265. Also, Fig. 3 , discloses the flow control logic 225 may then generate a MAC control pause frame including this source address information).

8. Claim 13 is rejected under 35 U.S.C. 103(a) as being unpatentable over Erimli in view of Levine and further in view of Kim et al. (US Patent Publication No. 2003/0219027).

**Regarding claim 13, (Previously Presented)** Erimli in view of Levine teach the method of claim 11, Erimli further teach the method wherein the signaling is performed (Column 7, lines 1-10 discloses the second switch may then transmit a similar MAC control pause frame on the port associated with the source address) but fail to teach the method using a non-memory-consuming communication to signal the first port of the first device. However, Kim et al. teach the method using a non-memory-consuming communication to signal the first port of the first device (Paragraph [0007] discloses the non-memory semiconductor performs a traffic transmission between ports in network equipment such as a router and switch, and performs a programming for an intelligent

switching function in such a way that various kinds of multimedia Internet traffic services are available).

Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to modify the method of Erimli to include the non-memory feature taught by Kim et al. in order to increase the speed of the communication and reduce the delay that is caused by buffers.

9. Claims 22 and 25 are rejected under 35 U.S.C. 103(a) as being unpatentable over Erimli (US Patent No. 6,980,520) in view of Leach, JR. et al (US Patent Publication No. 2002/0089994).

**Regarding claim 22,** (Currently Amended) Erimli teaches the device of claim 21 wherein, further comprising: a second communications means between the first data distribution means and the second data distribution means (Column 11, lines 21-28 disclose connection using other source addresses) but fail to explicitly teach the system wherein the second communications means that is non-lossy. However, Leach Jr et al. teach the system wherein the second communications means that is non-lossy (See paragraph [0008]).

Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to modify the communication means disclosed by Erimli to perform as a lossy less communication link taught by Leach, JR et al. in order to increase the quality of communication and decrease the delay caused by it.

**Regarding claim 25,** (Currently Amended) Erimli teaches the device of claim 24, wherein further comprising: a second communications means for allowing

communication between the first the second data distribution means is attached to, wherein the a second communications means (Column 11, lines 21-28 disclose connection using other source addresses), but fail to teach the system wherein the second communications means that is non-lossy. However, Leach, JR. et al teach the system wherein the second communications means that is non-lossy (See paragraph [0008]).

Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to modify the communication means disclosed by Erimli to perform as a lossy less communication link taught by Leach,, JR et al. in order to increase the quality of communication and decrease the delay caused by it.

### ***Response to Arguments***

10. Applicant's arguments filed 04/30/2009 have been fully considered but they are not persuasive. On page 9 of the Applicant's response, the Applicant argued that the prior art of the record fail to teach "determining, at the second device, an individual port on the first device that is causing oversubscription of the first port of the second device" cited in claim 1, 11, 21, 24, 31 and 33. The Examiner respectfully disagrees. As shown in column 7, lines 1-10, when a second switch receives the pause frame, it determines to stop sending data frames associated with the source address included in the pause frame to the first switch. The second switch may also forward a similar pause frame via the network. The depended claims remain rejected due to the above reasoning.

***Conclusion***

11. Any inquiry concerning this communication or earlier communications from the examiner should be directed to NIMA MAHMOUDZADEH whose telephone number is (571)270-3527. The examiner can normally be reached on Monday - Friday, 8am-5pm.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chirag G. Shah can be reached on (571) 272-3144. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
